Graded Exercise: IN2064 / Endterm
Examiner: Prof. Dr. Stephan Günnemann

Date: Tuesday 16th February, 2021
Time: 11:00 – 13:00

Working instructions

- This graded exercise consists of **36 pages** with a total of **10 problems**.
Please make sure now that you received a complete copy of the graded exercise.
- The total amount of achievable credits in this graded exercise is 48.
- This document is copyrighted and it is **illegal** for you to distribute it or upload it to any third-party websites.
- Do **not** submit the problem descriptions (this document) to TUMexam

Left room from _____ to _____ / Early submission at _____

Problem 1: Probabilistic Inference (Version A) (4 credits)

Imagine a disease spreading across a small village. To make accurate forecasts for the necessary hospital beds, you want to estimate the severity of the disease with the following model. Let s be a measure for the severity of a disease. We assume a priori that s follows a standard normal distribution.

$$s \sim \mathcal{N}(0, 1) \propto \exp(-s^2)$$

The severity probabilistically influences the required days of hospital care t for a patient according to

$$t | s \sim \text{Exp}(\lambda) = \lambda \exp(-\lambda t) \text{ where } \lambda = s^2.$$

After some time, you were able to collect $N = 5$ data points. The respective patients left the hospital after 3, 7, 3, 2 and 4 days.

Derive an a-posteriori most likely value of the severity s considering these observations. Justify your answer.

Note: You can assume that $s \neq 0$, that is, you can safely divide by s if necessary.

We have to find the most likely value s^* of s after incorporating the observations of t (the maximum a posteriori estimate)

$$\begin{aligned} s^* &= \underset{s}{\operatorname{argmax}} p(D|s)p(s) \\ &= \underset{s}{\operatorname{argmax}} \log p(D|s)p(s) \\ &= \underset{s}{\operatorname{argmax}} \sum_{i=1}^N \log s^2 \exp(-s^2 t_i) + \log \exp(-s^2) \\ &= \underset{s}{\operatorname{argmax}} N \log s^2 - s^2 \sum_{i=1}^N t_i - s^2 \\ &= \underset{s}{\operatorname{argmax}} N \log s^2 - s^2 (T+1) \text{ where } T = \sum_{i=1}^N t_i \end{aligned}$$

This expression is symmetric in the sign of s , so we can restrict ourselves to the case $s \geq 0$. On this restricted domain, the expression is also concave in s , so we can find the maximum by differentiation

$$\frac{\partial}{\partial s} N \log s^2 - s^2 (T+1) = \frac{2N}{s} - 2(T+1) = 0 \Rightarrow \frac{2N}{s} - 2T - 2 = 0 \Rightarrow \frac{2N}{s} = 2T + 2$$

$$\Rightarrow s = \sqrt{\frac{2N}{2T+2}} = \sqrt{\frac{N}{T+1}}$$

$$s^* = \sqrt{\frac{N}{T+1}} = \sqrt{\frac{1}{4}} = \frac{1}{2}$$

Problem 1: Probabilistic Inference (Version B) (4 credits)

Imagine a disease spreading across a small village. To make accurate forecasts for the necessary hospital beds, you want to estimate the severity of the disease with the following model. Let s be a measure for the severity of a disease. We assume a priori that s follows a standard normal distribution.

$$s \sim \mathcal{N}(0, 1) \propto \exp(-s^2)$$

The severity probabilistically influences the required days of hospital care t for a patient according to

$$t | s \sim \text{Exp}(\lambda) = \lambda \exp(-\lambda t) \text{ where } \lambda = s^2.$$

After some time, you were able to collect $N = 3$ data points. The respective patients left the hospital after 10, 11 and 5 days.

Derive an a-posteriori most likely value of the severity s considering these observations. Justify your answer.

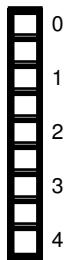

Note: You can assume that $s \neq 0$, that is, you can safely divide by s if necessary.

$$\begin{aligned} s^* &= \underset{s}{\operatorname{argmax}} P(D|s) P(s) = \underset{s}{\operatorname{argmax}} \log P(D|s) + \log P(s) \\ &= \underset{s}{\operatorname{argmax}} \sum_{i=1}^N \log s^2 \exp(-s^2 t_i) + \log \exp(-s^2) \\ &= \underset{s}{\operatorname{argmax}} N \log s^2 - s^2 \sum_{i=1}^N t_i - s^2 = \underset{s}{\operatorname{argmax}} N \log s^2 - s^2 (\tau + 1) \\ \frac{\partial}{\partial s} N \log s^2 - s^2 (\tau + 1) &= \frac{N 2s}{s \cdot s} - 2s (\tau + 1) = \frac{2N}{s} - 2s (\tau + 1) = 0 \end{aligned}$$

$$\frac{2N}{2(\tau+1)} = s^2 \quad ; \quad s = \sqrt{\frac{N}{\tau+1}}$$

$$\tau = 26$$

$$s^* = \sqrt{\frac{3}{27}} = \sqrt{\frac{1}{9}} = \frac{1}{3}$$

Problem 2: k-nearest neighbors (Version A) (4 credits)

Consider a k -nearest neighbor classifier using Euclidean distance on a binary classification task. The prediction for an instance is the *majority* class of its k -nearest neighbors. The training set is shown on Figure 4.1.

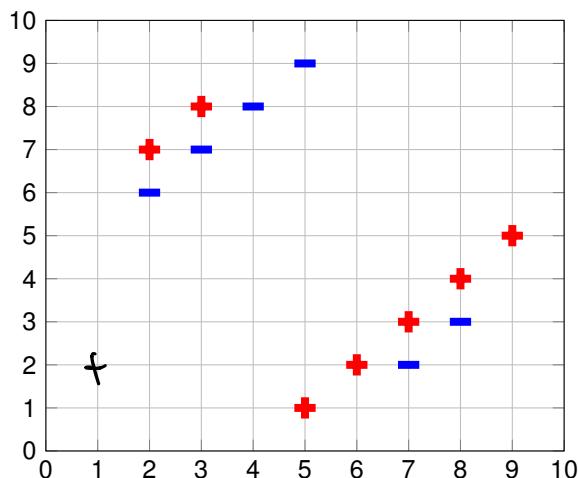

Figure 4.1: A red $+$ denotes instances from class 1, and a blue $-$ denotes instances from class 2.

- a) Specify one value of k that minimizes the leave-one-out cross-validation (LOOCV) error. Please consider only *odd* values of k (e.g. 1, 3, 5, 7, ...) to avoid ties. What is the resulting error, i.e. the number of misclassified data points?

$$k \leq 5$$

$$\text{resulting error} : \frac{4}{13}$$

- b) Imagine that the training dataset contains one additional point with coordinates $(1, 2)$ and label $+$. Would this change the decision boundary for a 1-nearest neighbor classifier? Why or why not?

Yes, One counter example is that $(1, 3)$ was previously labeled with $-$ but is now labeled $+$ since the new point $(1, 2)$ is closest

- c) If your answer above was *no* what is the *shortest* distance that you need to move $(1, 2)$ such that it changes the decision boundary? If your answer above was *yes* what is the *shortest* distance that you need to move $(1, 2)$ so it does not change the decision boundary?

Write down the new coordinates after moving and specify the shortest distance.

We need to move it to the closest data point with the same label to keep the decision boundary the same. In this case this is $(5, 1)$. The distance is $\sqrt{1^2 + 4^2} = \sqrt{17}$

Problem 3: Linear Regression (Version A) (6 credits)

Consider a dataset $\mathcal{D} = \{(\mathbf{x}^{(i)}, y^{(i)})\}_{i=1}^N$, with $\mathbf{x}^{(i)} \in \mathbb{R}^D$, $y^{(i)} \in \mathbb{R}$ and centered features so that $\frac{1}{N} \sum_{i=1}^N \mathbf{x}^{(i)} = \mathbf{0}$. During preprocessing, we absorb the bias as a constant feature to produce the transformed dataset $\tilde{\mathcal{D}} = \{(\tilde{\mathbf{x}}^{(i)}, \tilde{y}^{(i)})\}_{i=1}^N$ where we map each $(\mathbf{x}^{(i)}, y^{(i)})$ to

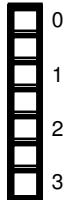

$$\tilde{\mathbf{x}}^{(i)} = \begin{pmatrix} \mathbf{x}^{(i)} \\ 1 \end{pmatrix} \in \mathbb{R}^{D+1} \quad \text{and} \quad \tilde{y}^{(i)} = y^{(i)}.$$

We want to perform ridge regression with regularization strength λ to find the optimal weight vector $\tilde{\mathbf{w}}^* \in \mathbb{R}^{D+1}$.

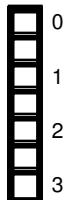

Reminder: In ridge regression we optimize the loss function

$$\mathcal{L}(\tilde{\mathbf{w}}) = \frac{1}{2} \sum_{i=1}^N (\tilde{\mathbf{w}}^\top \tilde{\mathbf{x}}^{(i)} - \tilde{y}^{(i)})^2 + \frac{\lambda}{2} \|\tilde{\mathbf{w}}\|_2^2.$$

- a) Derive the closed form solution for the last element of the weight vector $\tilde{\mathbf{w}}_{D+1}^*$ corresponding to the absorbed bias obtained from ridge regression on $\tilde{\mathcal{D}}$.

- b) Propose an alternative *preprocessing step*, i.e. define an alternative transformed dataset $\hat{\mathcal{D}} = \{(\hat{\mathbf{x}}^{(i)}, \hat{y}^{(i)})\}_{i=1}^N$, such that the optimal ridge regression vector $\hat{\mathbf{w}}^* \in \mathbb{R}^D$ on $\hat{\mathcal{D}}$ is equivalent to $\tilde{\mathbf{w}}^*$ obtained on $\tilde{\mathcal{D}}$. Justify that ridge regression on your preprocessed data $\hat{\mathcal{D}}$ finds an optimal $\hat{\mathbf{w}}^* \in \mathbb{R}^D$ that is equal to $\tilde{\mathbf{w}}^*$ in the first D elements, i.e. $\hat{\mathbf{w}}_i^* = \tilde{\mathbf{w}}_i^*$ for $i \in \{1, \dots, D\}$. You do not need to derive the closed-form solution for $\hat{\mathbf{w}}^*$.

Problem 3: Linear Regression (Version B) (6 credits)

Consider a dataset $\mathcal{D} = \{(\mathbf{x}^{(i)}, y^{(i)})\}_{i=1}^N$, with $\mathbf{x}^{(i)} \in \mathbb{R}^D$, $y^{(i)} \in \mathbb{R}$ and centered features so that $\frac{1}{N} \sum_{i=1}^N \mathbf{x}^{(i)} = \mathbf{0}$. During preprocessing, we absorb the bias as a constant feature to produce the transformed dataset $\tilde{\mathcal{D}} = \{(\tilde{\mathbf{x}}^{(i)}, \tilde{y}^{(i)})\}_{i=1}^N$ where we map each $(\mathbf{x}^{(i)}, y^{(i)})$ to

$$\tilde{\mathbf{x}}^{(i)} = \begin{pmatrix} \mathbf{x}^{(i)} \\ 1 \end{pmatrix} \in \mathbb{R}^{D+1} \quad \text{and} \quad \tilde{y}^{(i)} = y^{(i)}.$$

We want to perform ridge regression with regularization strength λ to find the optimal weight vector $\tilde{\mathbf{w}}^* \in \mathbb{R}^{D+1}$.

Reminder: In ridge regression we optimize the loss function

$$\mathcal{L}(\tilde{\mathbf{w}}) = \frac{1}{2} \sum_{i=1}^N (\tilde{\mathbf{w}}^\top \tilde{\mathbf{x}}^{(i)} - \tilde{y}^{(i)})^2 + \frac{\lambda}{2} \|\tilde{\mathbf{w}}\|_2^2.$$

- 0 a) Derive the closed form solution for the last element of the weight vector $\tilde{\mathbf{w}}_{D+1}^*$ corresponding to the absorbed bias obtained from ridge regression on $\tilde{\mathcal{D}}$.

Problem 4: Naive Bayes (Version A) (6 credits)

We have collected the dataset shown in the table below with the continuous feature x_1 , and the discrete feature x_2 that can take either of the values yes or no. Each data point is labeled as one of three classes 1, 2 or 3 denoted by y .

Table 10.1: Naive Bayes Data (each column is one data point)

| | (1) | (2) | (3) | (4) | (5) | (6) | (7) |
|-------|-----|-----|------|------|-----|-----|-----|
| x_1 | 0.0 | 2.0 | -2.0 | -1.0 | 3.0 | 4.0 | 6.0 |
| x_2 | yes | no | no | yes | no | yes | yes |
| y | 1 | 1 | 2 | 2 | 2 | 3 | 3 |

- a) Set up a naive Bayes classifier (choose likelihoods and their parameterization) for the data in Table 10.1 using Normal distributions with fixed variance of 1 and Bernoulli distributions. Compute the maximum likelihood estimate of all parameters θ required for naive Bayes.

$$x_1 | y = c \sim N(\mu_c, 1) \quad x_2 | y = c \sim \text{Bernoulli}(\alpha_c)$$

$$y \sim \text{Categorical}(\pi) \quad \pi = \left(\frac{2}{7}, \frac{3}{7}, \frac{2}{7} \right)^T \quad \mu_1 = 1 \quad \mu_2 = 0 \quad \mu_3 = 5$$

$$\alpha_1 = \frac{1}{2} \quad \alpha_2 = \frac{1}{2} \quad \alpha_3 = 1$$

- b) You observe a new data point $\mathbf{x}^{(b)} = (1 \text{ yes})$. Compute the unnormalized posterior over classes $p(y^{(b)} | \mathbf{x}^{(b)}, \theta)$ for $\mathbf{x}^{(b)}$. Simplify as far as possible without evaluating exponential functions, square roots, logarithms, etc. Briefly justify how you arrive at your solution. What is the most likely class for this data point?

| |
|---|
| 0 |
| 1 |
| 2 |
| 3 |

- c) Next, you get another data point $\mathbf{x}^{(d)} = (\text{n/a } \text{n/a})$, where all values are missing. Compute the unnormalized posterior over classes $p(y^{(d)} | \mathbf{x}^{(d)}, \theta)$ for $\mathbf{x}^{(d)}$. Simplify as far as possible without evaluating exponential functions, square roots, logarithms, etc. Briefly justify how you arrive at your solution. What is the most likely class for this data point?

| |
|---|
| 0 |
| 1 |

- d) Finally, you see a data point $\mathbf{x}^{(c)} = (\text{n/a } \text{no})$, i.e. the features are only partially known. Compute the unnormalized posterior over classes $p(y^{(c)} | \mathbf{x}^{(c)}, \theta)$ for $\mathbf{x}^{(c)}$. Simplify as far as possible without evaluating exponential functions, square roots, logarithms, etc. Briefly justify how you arrive at your solution. What is the most likely class for this data point?

What is the most likely class for this data point?
- 1 

- 0  d) Finally, you see a data point $\mathbf{x}^{(c)} = (\text{n/a } \text{no})$, i.e. the features are only partially known. Compute the unnormalized posterior over classes $p(y^{(c)} | \mathbf{x}^{(c)}, \theta)$ for $\mathbf{x}^{(c)}$. Simplify as far as possible without evaluating exponential functions, square roots, logarithms, etc. Briefly justify how you arrive at your solution. What is the most likely class for this data point?
- 1 

Problem 5: Optimization (Version A) (2 credits)

Suppose that $\mathbf{a} \in \mathbb{R}^d$ is some fixed vector. We define the function $f : \mathbb{R}^d \rightarrow \mathbb{R}$ as

$$f(\mathbf{x}) = \exp(\mathbf{a}^T \mathbf{x} + e^{-\mathbf{a}^T \mathbf{x}}).$$

Prove or disprove that f is convex on \mathbb{R}^d .

| |
|---|
| 0 |
| 1 |
| 2 |

$\mathbf{a}^T \mathbf{x}$ is convex in \mathbf{x} and e^z is an increasing convex function.
Therefore, their composition $e^{\mathbf{a}^T \mathbf{x}}$ is convex in \mathbf{x} .
Similarly, $-e^z$ is convex in \mathbf{x} , so $e^{-\mathbf{a}^T \mathbf{x}}$ is convex in \mathbf{x} .
Finally, $\exp(e^{\mathbf{a}^T \mathbf{x}} + e^{-\mathbf{a}^T \mathbf{x}})$ is a composition of e^z (an increasing convex function) with another convex function.
Therefore $f(\mathbf{x})$ is convex \Rightarrow

Problem 6: Convolutional Neural Networks (Version A) (3 credits)

Recall that a convolutional layer is defined by the following parameters:

- C_{in} — number of input channels
- C_{out} — number of output channels
- K — kernel (sliding window) size
- P — padding size
- S — stride

Suppose that \mathbf{x} is an image with height 64 and width 32 (in pixels) that has 3 channels, which we can represent as a tensor (three dimensional array) of shape [3, 64, 32].

We passed \mathbf{x} through a neural network consisting of two convolutional layers conv1 and conv2 (in this order). As output we obtained a tensor of shape [16, 16, 8] (i.e., 16 channels, height 16 and width 8).

We know that the first convolutional layer conv1 has the following parameters

- $C_{\text{in}} = 3$
- $C_{\text{out}} = 32$
- $K = 3$
- $P = 1$
- $S = 4$

We also know that the second convolutional layer conv2 has kernel size $K = 3$.

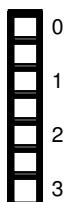

What are the remaining parameters $C_{\text{in}}, C_{\text{out}}, P, S$ of the second convolutional layer conv2? Justify your answer.

$$[3, 64, 32] \rightarrow [32, 16, 8]$$

$$\begin{aligned}
 C_{\text{in}} &= 32 \\
 C_{\text{out}} &= 16 \\
 P &= 1 \\
 S &= 1
 \end{aligned}$$

$$\begin{aligned}
 16 + 2(P) - 3 &= 16 \\
 16 + 2 \cdot 1 - 3 &= 16 \\
 16 + 2 - 3 &= 16 \\
 15 &= 16
 \end{aligned}$$

$$\begin{aligned}
 15S &= 16 + 2P - 3 \\
 15S &= 16 + 2 \cdot 1 - 3 \\
 15S &= 15 \\
 S &= 1
 \end{aligned}$$

Problem 7: SVMs (Version A) (5 credits)

Consider a soft-margin SVM trained on a binary classification task with some fixed and finite penalty C , i.e. $0 < C < \infty$. Assume that the training set contains at least two instances from each class. After training you observe that the optimal slack variables are zero for all instances except for a *single* instance q . Specifically, $\xi_q > 2$ for q and $\xi_i = 0$ for all $i \neq q$. Let $m_{\text{soft}} = \frac{2}{\|\mathbf{w}_{\text{soft}}\|}$ be the optimal margin where \mathbf{w}_{soft} are the optimal weights.

- a) Now you remove the instance q from the dataset and you train a new *hard-margin* SVM. Let m_{hard} be the resulting optimal margin. Which one of the following holds: $m_{\text{hard}} \leq m_{\text{soft}}$, $m_{\text{hard}} = m_{\text{soft}}$, $m_{\text{hard}} \geq m_{\text{soft}}$. Justify your answer.

Since $\xi_q > 2$, the instance q is misclassified and lies on the wrong side of the decision boundary and it is outside the margin. The vector \mathbf{w}_{soft} is a feasible solution for the new hard-margin SVM, i.e. it satisfies all the constraints because:

- By removing instance q we remove the corresponding constraint

- All other instances $i \neq q$ satisfy $y_i(\mathbf{w}_{\text{soft}}^T \mathbf{x}_i + b) \geq 1$ since $\xi_i = 0$

Since we already found one feasible solution, namely \mathbf{w}_{soft} with the corresponding margin $M_{\text{soft}} = \frac{2}{\|\mathbf{w}_{\text{soft}}\|}$, the solution found by the hard-margin SVM with q removed can only be larger. Therefore, $M_{\text{hard}} \geq M_{\text{soft}}$.

- b) Now instead of removing it, you relabel the instance q (if before it was class -1 you set it to class $+1$ and vice versa) and you train a new *hard-margin* SVM. Let m_{hard} be the resulting optimal margin. Which one of the following holds: $m_{\text{hard}} \leq m_{\text{soft}}$, $m_{\text{hard}} = m_{\text{soft}}$, $m_{\text{hard}} \geq m_{\text{soft}}$. Justify your answer.

Since $\xi_q > 2$ the instance q is misclassified and lies on the wrong side of the decision boundary and it is outside of the margin.

As before, the vector \mathbf{w}_{soft} is a feasible solution for the new hard-margin SVM, i.e. it satisfies all of the constraints.

The constraint for instance q before was $y_q(\mathbf{w}_{\text{soft}}^T \mathbf{x}_q + b) \geq 1 - \xi_q$. The optimal solution for

$$\xi_q \begin{cases} 1 - y_q(\mathbf{w}_{\text{soft}}^T \mathbf{x}_q + b), & \text{if } y_q(\mathbf{w}_{\text{soft}}^T \mathbf{x}_q + b) \geq 1 \\ 0 & \text{otherwise} \end{cases}$$

$\xi_q > 2$, implies $y_q(\mathbf{w}_{\text{soft}}^T \mathbf{x}_q + b) \geq -1$. If we now flip the sign of $-y_q = \tilde{y}_q$, we get $\tilde{y}_q(\mathbf{w}_{\text{soft}}^T \mathbf{x}_q + b) \geq 1$.

Hence $\tilde{\xi}_q = 0$ (instance q is now correctly classified and outside the margin). As before, all other instances $i \neq q$ satisfy $y_i(\mathbf{w}_{\text{soft}}^T \mathbf{x}_i + b) \geq 1$ since $\xi_i = 0$.

Substituting $\xi_q > 2$ we have $y_q(\mathbf{w}_{\text{soft}}^T \mathbf{x}_q + b) \geq -1$. By relabeling instance q , i.e. multiplying y_q by -1 the hard-margin constraint is satisfied.

Since we already found one feasible solution, namely \mathbf{w}_{soft} with the corresponding $M_{\text{soft}} = \frac{2}{\|\mathbf{w}_{\text{soft}}\|}$,

the solution found by the hard-margin SVM with q relabeled can only be larger or be as large ($M_{\text{hard}} \geq M_{\text{soft}}$ || $M_{\text{hard}} = M_{\text{soft}}$)

Problem 7: SVMs (Version B) (5 credits)

Consider a soft-margin SVM trained on a binary classification task with some fixed and finite penalty C , i.e. $0 < C < \infty$. Assume that the training set contains at least two instances from each class. After training you observe that the optimal slack variables are zero for all instances except for a *single* instance q . Specifically, $\xi_q > 2$ for q and $\xi_i = 0$ for all $i \neq q$. Let $m_{\text{soft}} = \frac{2}{\|\mathbf{w}_{\text{soft}}\|}$ be the optimal margin where \mathbf{w}_{soft} are the optimal weights.

- 0 a) Now you *remove* the instance q from the dataset and you train a new *hard-margin* SVM. Let m_{hard} be the resulting optimal margin. Which one of the following holds: $m_{\text{hard}} \leq m_{\text{soft}}$, $m_{\text{hard}} = m_{\text{soft}}$, $m_{\text{hard}} \geq m_{\text{soft}}$. Justify your answer.

2
3

- 0 b) Now instead of removing it, you *relabel* the instance q (if before it was class -1 you set it to class $+1$ and vice versa) and you train a new *hard-margin* SVM. Let m_{hard} be the resulting optimal margin. Which one of the following holds: $m_{\text{hard}} \leq m_{\text{soft}}$, $m_{\text{hard}} = m_{\text{soft}}$, $m_{\text{hard}} \geq m_{\text{soft}}$. Justify your answer.

Problem 8: Low-rank Approximation and Regression (Version A) (6 credits)

Consider a dataset $\mathcal{D} = \{(\mathbf{x}^{(i)}, y^{(i)})\}_{i=1}^N$, with $\mathbf{x}^{(i)} \in \mathbb{R}^D, y^{(i)} \in \mathbb{R}$. Let $\mathbf{X} \in \mathbb{R}^{N \times D}$ be the matrix of features and $\mathbf{y} \in \mathbb{R}^N$ be the vector of regression targets.

We construct the matrix $\mathbf{M} = [\mathbf{X}, \mathbf{y}] \in \mathbb{R}^{N \times (D+1)}$ where \mathbf{y} has been appended as an additional column to \mathbf{X} . Let $\mathbf{M}' \in \mathbb{R}^{N \times (D+1)}$ be the best rank K approximation of \mathbf{M} for some chosen constant K . Define $\mathbf{M}' = [\mathbf{X}', \mathbf{y}']$ where \mathbf{X}' is the matrix containing the first D columns of \mathbf{M}' and \mathbf{y}' is the last column of \mathbf{M}' .

We will fit a standard linear regression model using \mathbf{X}' as the feature matrix and \mathbf{y}' as the target, i.e. we find the optimal weight vector $\mathbf{w}^* \in \mathbb{R}^D$ and the bias $b^* \in \mathbb{R}$. Careful: We do regression on \mathbf{X}' and \mathbf{y}' not on \mathbf{X} and \mathbf{y} !

- a) Consider the case where $D = 1$ and $K = 1$, i.e. our features are one dimensional and \mathbf{M}' is the best rank 1 approximation of \mathbf{M} . Assuming the features \mathbf{X}' contain at least two distinct elements, what is the training error achieved by the optimal \mathbf{w}^* and b^* ? Justify your answer.

The training error is 0. Since \mathbf{M}' is a rank 1 matrix \mathbf{X}' and \mathbf{y}' are linearly dependent which means we can perfectly reconstruct \mathbf{y}' from \mathbf{X}'

| <input type="checkbox"/> | 1 |
| <input type="checkbox"/> | 2 |
| <input type="checkbox"/> | |

- b) For the same case as in (a) where $D = 1$ and $K = 1$, write down the optimal \mathbf{w}^* and b^* in terms of the singular value decomposition of $\mathbf{M} = \mathbf{U}\Sigma\mathbf{V}^T$, i.e. write down \mathbf{w}^* and b^* as a function of the singular values and singular vectors $\mathbf{u}_i, \sigma_i, \mathbf{v}_i$.

$$\mathbf{w}^* \mathbf{X}' + b^* = \mathbf{y}'$$

\mathbf{M}' is the best rank 1 approximation of \mathbf{M} , we have: $\mathbf{M}' = \sigma_1 \mathbf{u}_1 \mathbf{v}_1^T$, where σ_1 is the largest singular value, and \mathbf{u}_1 and \mathbf{v}_1 the corresponding singular vectors

$$\mathbf{X}' = \sigma_1 \mathbf{u}_1 \mathbf{v}_1^T \quad \mathbf{y}' = \sigma_1 \mathbf{u}_1 \mathbf{v}_{12}$$

$$\mathbf{w}^* \mathbf{X}' + b^* = \mathbf{y}'$$

$$\mathbf{w}^* \sigma_1 \mathbf{u}_1 \mathbf{v}_{12} + b^* = \sigma_1 \mathbf{u}_1 \mathbf{v}_{12}$$

$$\mathbf{w}^* \sigma_1 \mathbf{u}_1 \mathbf{v}_{11} + b^* = \mathbf{v}_{12} \quad b^* = 0 \quad \mathbf{w}^* = \frac{\mathbf{v}_{12}}{\sigma_1 \mathbf{u}_1}$$

- c) Consider the general case of D -dimensional ($D > 1$) feature vectors and a rank K approximation of \mathbf{M} . Assuming that \mathbf{X}' is full rank, what is the training error achieved by the optimal \mathbf{w}^* and b^* as a function of K ?

Problem 9: K-means (Version A) (6 credits)

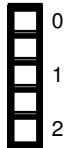

Consider a variant of K -means that uses the (squared) Mahalanobis distance

$$d(\mathbf{x}_i, \mathbf{x}_j) = (\mathbf{x}_i - \mathbf{x}_j)^T \boldsymbol{\Sigma}^{-1} (\mathbf{x}_i - \mathbf{x}_j), \quad (1)$$

with the covariance matrix $\boldsymbol{\Sigma}$, instead of the L_2 distance.

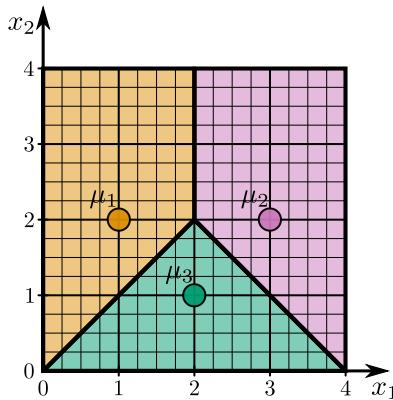

Hint: $\frac{\partial \mathbf{a}^T \mathbf{X} \mathbf{a}}{\partial \mathbf{a}} = (\mathbf{X} + \mathbf{X}^T) \mathbf{a}^T$

a) Derive the K -means cluster assignment and centroid updates for the (squared) Mahalanobis distance.

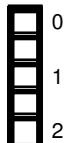

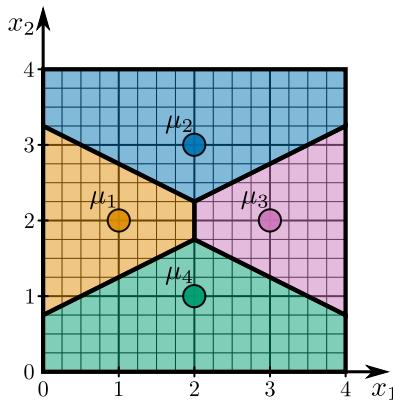

b) Instead of considering data samples we will now consider how the cluster centroids μ_i (which are given and fixed) partition the space into K parts. Every part is defined as the space of all points $\mathbf{x} \in \mathbb{R}^d$ that would be assigned to the corresponding cluster k using the (squared) Mahalanobis distance.

Consider the following result using the (squared) Mahalanobis distance with $\boldsymbol{\Sigma}^{-1}$, where the parts are denoted by the colors orange, pink, and green. Specify a possible $\boldsymbol{\Sigma}^{-1}$ that leads to this partitioning. Justify your answer.

Hint: Consider the boundary between two partitions. Furthermore, the inverse of a symmetric matrix is also symmetric, and the inverse of a positive/negative (semi-)definite matrix is also positive/negative (semi-)definite.

c) Consider the following result using the (squared) Mahalanobis distance with $\boldsymbol{\Sigma}^{-1}$, where the parts are denoted by the colors blue, orange, pink, and green. Specify a possible $\boldsymbol{\Sigma}^{-1}$ that leads to this partitioning. Justify your answer.
